Missing data mechanisms

Relation between the missingness indicators M and the data $Y = (Y_{obs}, Y_{mis})$ defines the mechanism behind the missing data

We distinguish

- missing completely at random (MCAR)
- missing at random (MAR)
- missing not at random (MNAR)

Introduced by Rubin (1976)

1. Missing Completely at Random (MCAR)

$$P(M = 1 \mid Y_{obs}, Y_{mis}) = P(M = 1)$$
 $M \text{ indicator: 0 if observed 1 if missing}$
 $Y_{obs} \text{ observed data}$
 $Y_{mis} \text{ unobserved data}$

- The probability of a value being missing does not depend on any other values (observed or unobserved)
- Observations with and without missing values are exchangeable, so those without missing values are representative for the rest
- Example: lab results gets lost in the mail

2. Missing at Random (MAR)

$$P(M = 1 \mid Y_{obs'} \mid Y_{mis}) = P(M = 1 \mid Y_{obs})$$

- Chance of missing observation depends on observed data only
- Example: patients with low blood pressure are measured less frequently than patients with high blood pressure
- You can estimate what the missing values should be based on observed data (in the example, the measured blood pressure)
- Observations with and without missing values differ on certain measured characteristics
- By comparing people with and without missing values, you can distinguish MCAR and MAR (e.g. Little's test, mcartest)

3. Missing not at random (MNAR)

$$P(M = 1 \mid Y_{obs}, Y_{mis})$$
 or $P(M = 1 \mid Y_{mis})$, do not simplify

- Missing values determine the probability of being missing even after conditioning on $Y_{\rm obs}$
- Examples:
 - Depression questionnaire is not completed if patient is depressed
 - Doctor does not record weight of a patient, because he sees that the patient is not obese
- Difficult. You cannot reconstruct the missing values using measured factors,
 have to make assumptions that you cannot verify
- Perform sensitivity analysis to calculate results under different assumptions for the missing mechanism
- Cannot determine from the data whether missing at random or not at random (!)

MCAR, MAR, MNAR?

Some depressed people have not filled in their income in a survey

Depressed people with a low income are less likely to fill in their income

An MRI measurement is performed in 30% of the participants in a study

Overview

1. Types of missing data (recap repeated measurements course)

2. Methods to deal with missing data

- 3. Multiple imputation
- 4. Practical exercises in R

Depends on

- 1. missings in outcome or exposure or confounder,
- 2. missings dependent on outcome?
- 3. missing mechanism (MCAR, MAR, MNAR)
- 4. the target parameter itself

Y – continuous outcome , A – continuous exposure

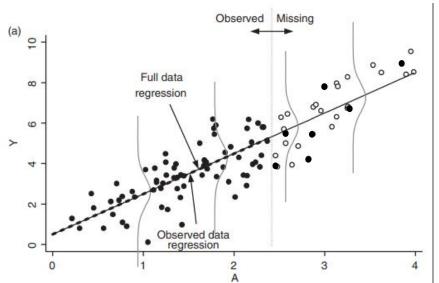

Example 1:

Y values are missing for 75% of observations with A>2.5

Missing mechanism?

Can we estimate the mean of Y in full population from observed data?

Can we estimate the effect of A on Y from observed data?

Examples taken from: Rhian et al. Using causal diagrams to guide analysis in missing data problems. SMMR 2011

Y – continuous outcome , A – continuous exposure

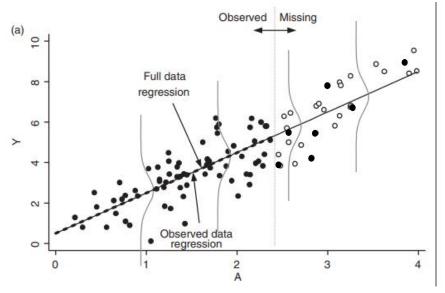

Example 1:

Y values are missing for 75% of observations with A>2.5

Missing mechanism? -> MAR

Can we estimate the mean of Y in full population from observed data? -> no

Can we estimate the effect of A on Y from observed data? -> yes

Y – continuous outcome , A – continuous exposure

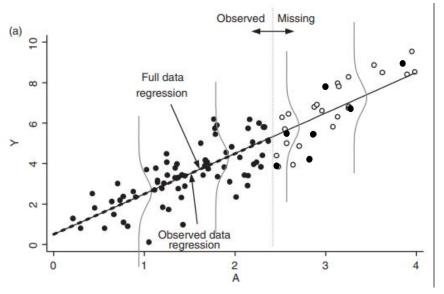

Example 2:

A values are missing for 75% of observations with A>2,5

Missing mechanism?

Can we estimate the mean of Y in full population from observed data?

Can we estimate the effect of A on Y from observed data?

Y – continuous outcome , A – continuous exposure

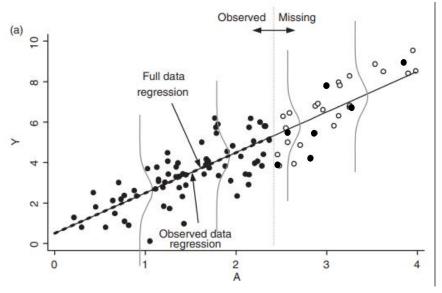

Example 2:

A values are missing for 75% of observations with A>2,5

Missing mechanism? -> MNAR

Can we estimate the mean of Y in full population from observed data? -> yes

Can we estimate the effect of A on Y from observed data? -> yes

Y – continuous outcome , A – continuous exposure

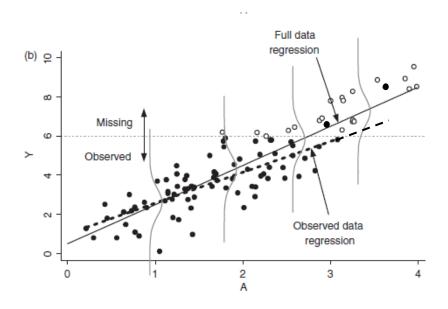

Example 3:

90% of Y values are missing for Y>6

Missing mechanism?

Can we estimate the mean of Y in full population from observed data?

Can we estimate the effect of A on Y from observed data?

Y – continuous outcome, A – continuous exposure

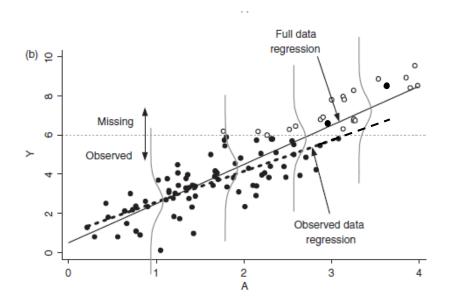

Example 3:

90% of Y values are missing for Y>6

Missing mechanism? -> MNAR

Can we estimate the mean of Y in full population from observed data? -> no

Can we estimate the effect of A on Y from observed data? -> no

How to handle missing values in the analysis?

Use only observed data / "complete cases"

- If all incomplete variables are expected to be MCAR
- will decrease efficiency (ie larger standard errors / p-values etc)
- If the number of missing observations is small (<5%), bias (and loss of efficiency)
 will not be large

YES, if possible

How to handle missing values in the analysis?

- Make a separate category/ indicator variable for missing
 - Used in some prediction algorithms¹
 - Interpretation typically only useful if the missing mechanism in future data is similar
- Fill in average (or median) values for missing data
 - May lead to dilution of effects if used on exposure variable
 - Useful in certain specific cases, e.g. missing values in covariates that only affect the outcome²
 - Single imputation will yield too small estimates of standard errors for imputed variables

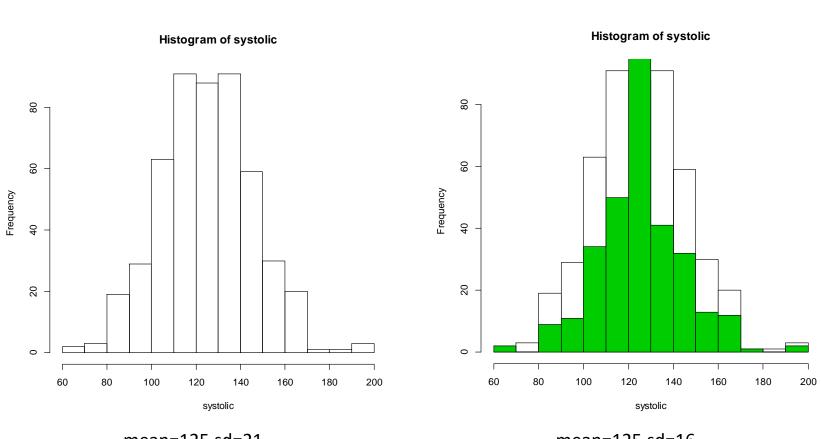

Only in special cases

Twala et al 2008 Pattern Recognition letters. Good methods for coping with missing data in decision trees

^{2.} White ad Thompson 2004 Stat Med Adjusting for partially missing baseline measurements in randomized trials

Single imputation will yield too small estimates of standard errors

replace half of the observations by the mean

mean=125 sd=21

mean=125 sd=16

Other approaches (assuming MAR)

- Maximum likelihood methods:
 - Mixed models (for missing values in repeatedly measured outcome variables)
 - Difficult to use when missing values occur in several variables (exposures, confounders and outcome)
- Inverse probability weighting
 - Estimate for each observation the probability to have missing value
 - Observations with a high probability to be missing will get higher weight
- Multiple Imputation

Yes, generally safe

In summary: when to use which analysis method

- First: think about the most plausible mechanism that led to the missing observations
- Choose appropriate analysis strategy
 - MCAR in all variables -> complete cases are unbiased, consider multiple imputation only for efficiency gain
 - MAR/MNAR but not dependent on outcome -> complete cases may still be unbiased for some analyses, consider multiple imputation for efficiency gain
 - MAR with dependency on outcome:
 - maximum likelihood method available?
 - no -> multiple imputation
 - MNAR with dependency on outcome:
 - sensitivity analysis

Rule of thumb: <5% missing data -> complete cases probably ok in any case

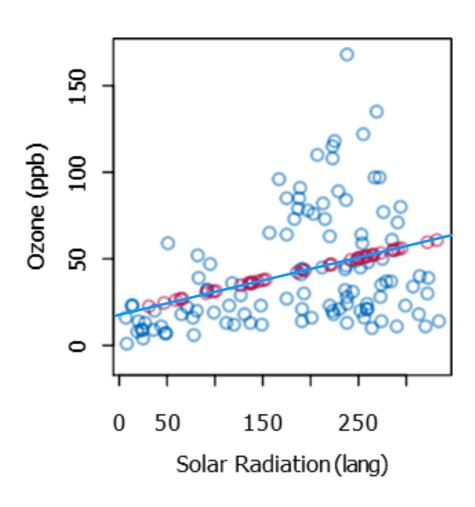

Overview

- 1. Types of missing data (recap repeated measurements course)
- 2. Methods to deal with missing data

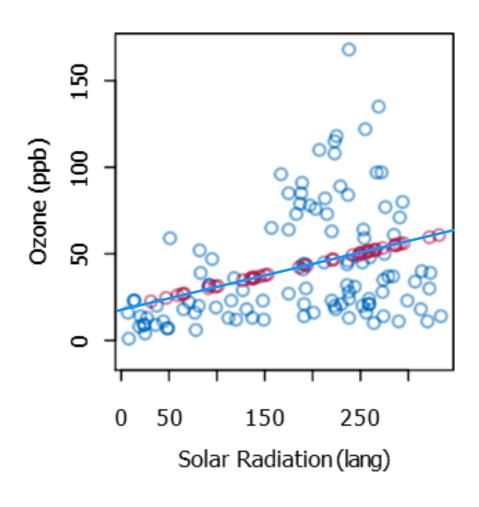

3. Multiple imputation

4. Practical exercises in R

What if we fill in missing values based on regression between exposure and outcome?

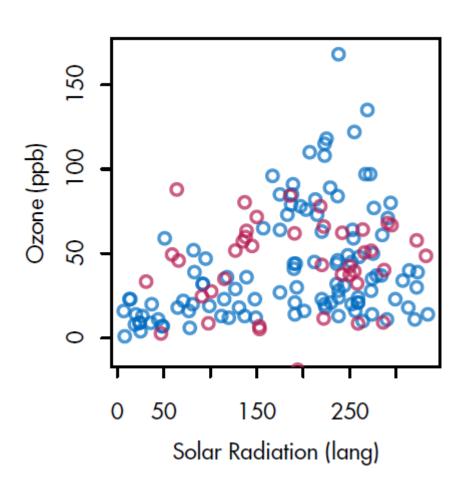

What if we fill in missing values based on regression between exposure and outcome?

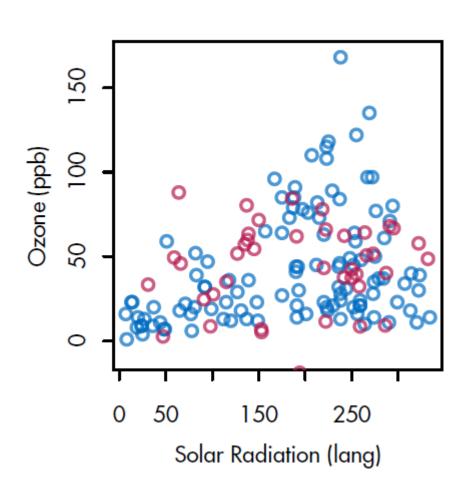

- means ok
- too strong correlation
- wrong confidence intervals / p-values

We need to use both regression and account for variability – single imputation

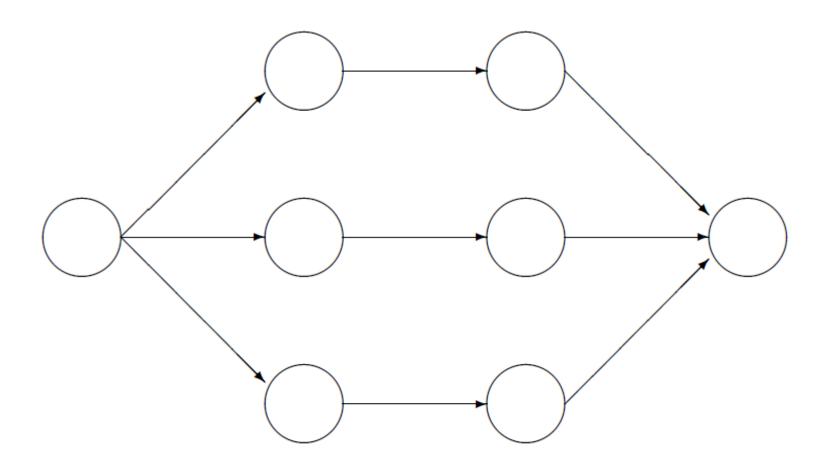

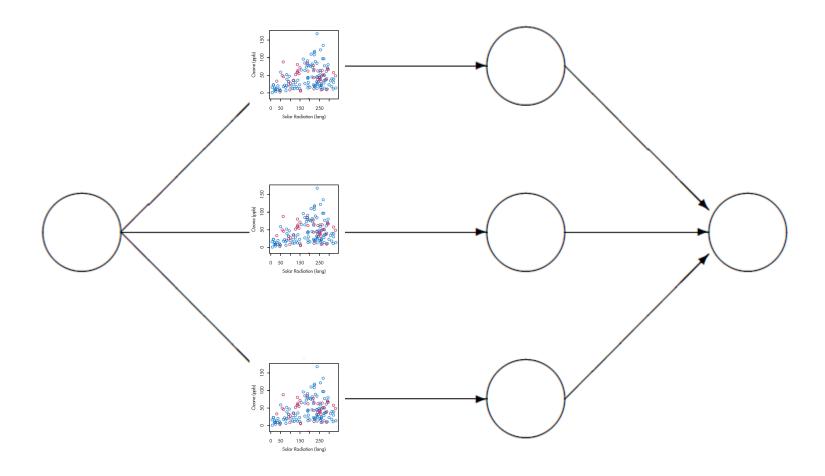

- means ok
- correlation ok

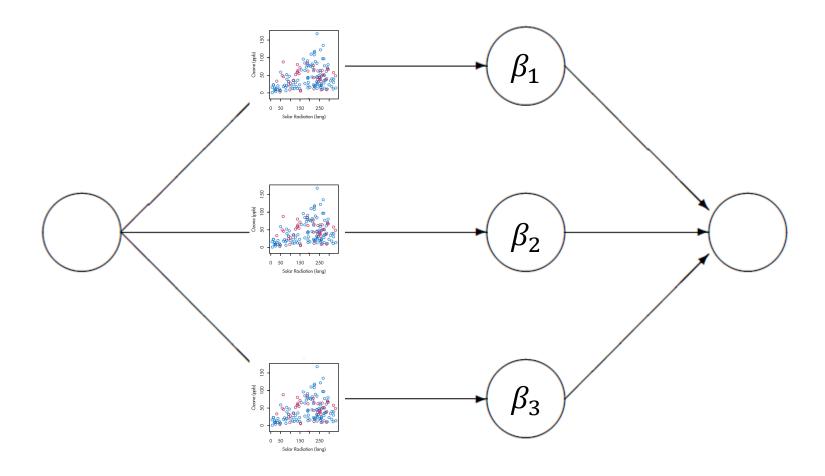

We need to use both regression and account for variability – single imputation

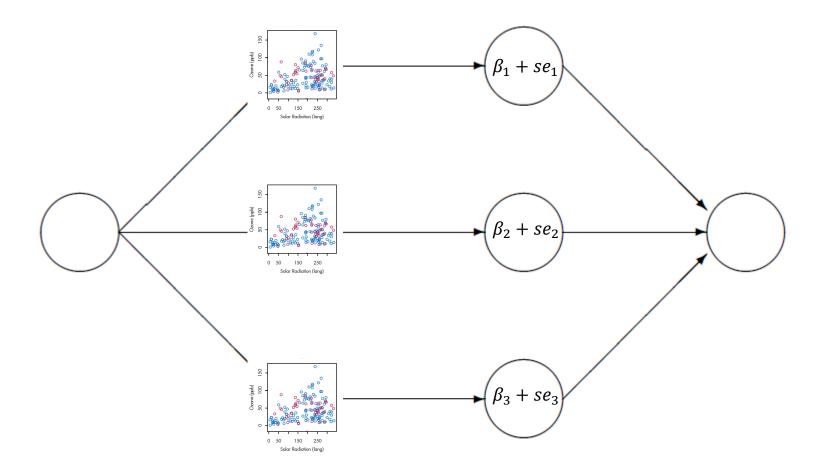

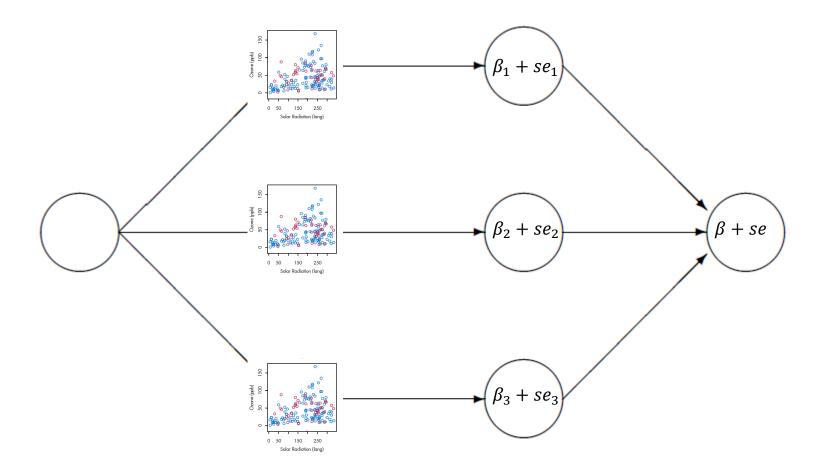

- means ok
- correlation ok
- BUT: still wrong confidence intervals / pvalues!!
- Need to 'confess' that we did not observe all these data!

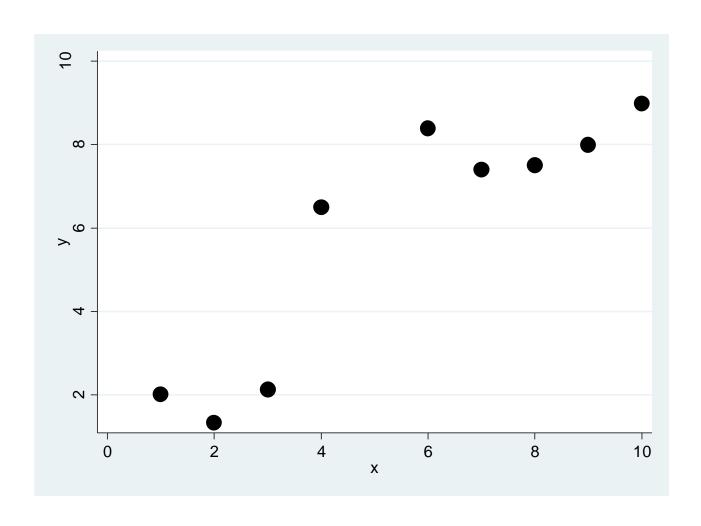

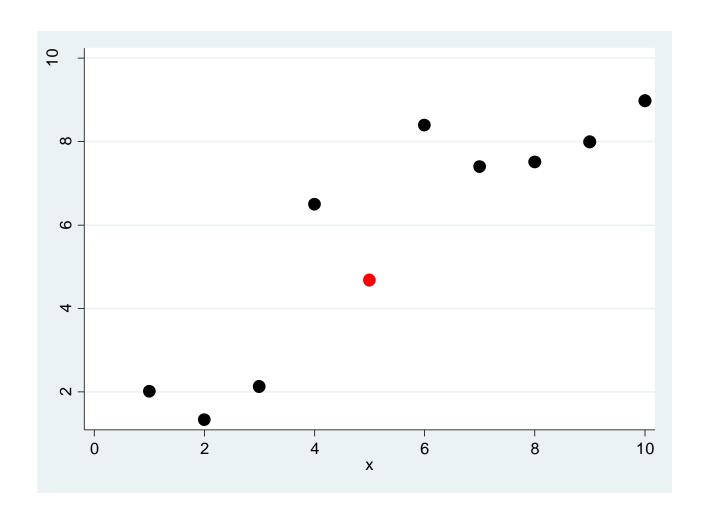

How is the missing Y value being imputed? Regression method:

- 1. Formulate imputation model
 - $y = \beta_0 + \beta_1 x + e$
 - $e^{N}(0, \tau^2)$
- 2. Fit the model, using observed data.
- 3. Draw values for β_0 , β_1 , and τ^2 , based on estimated coefficients and standard errors
- 4. Use the resulting imputation model to draw values for missing observations
- 5. This yields a complete dataset
- 6. Analyse the complete dataset and obtain an estimate with standard error

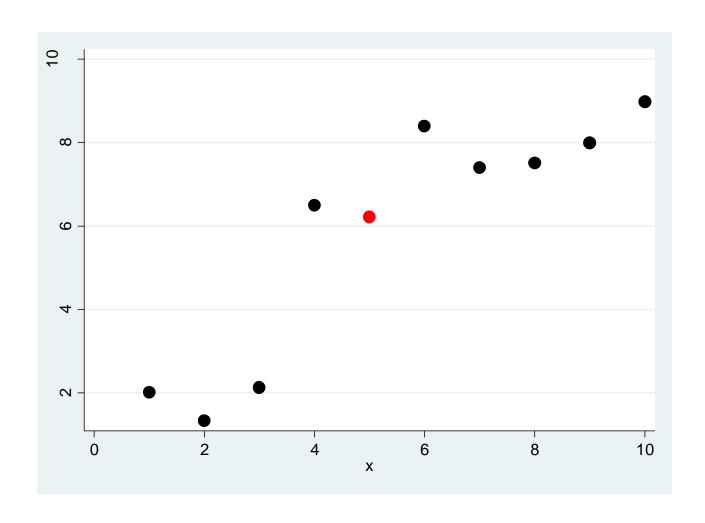

Example: Y is missing for x=5

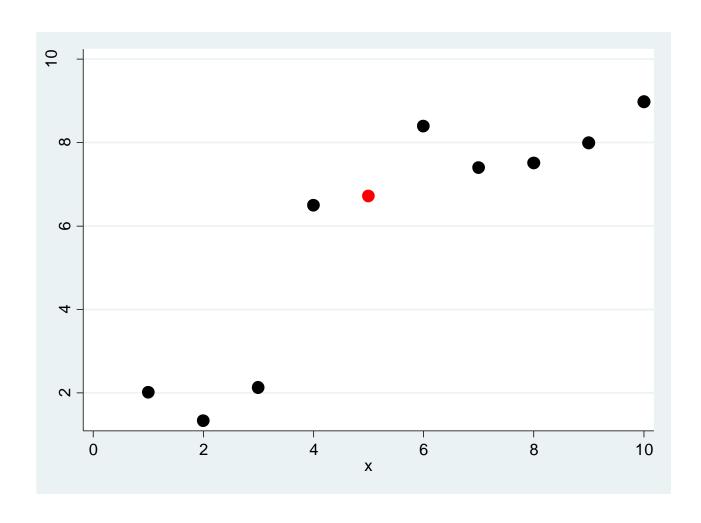

Imputation 1

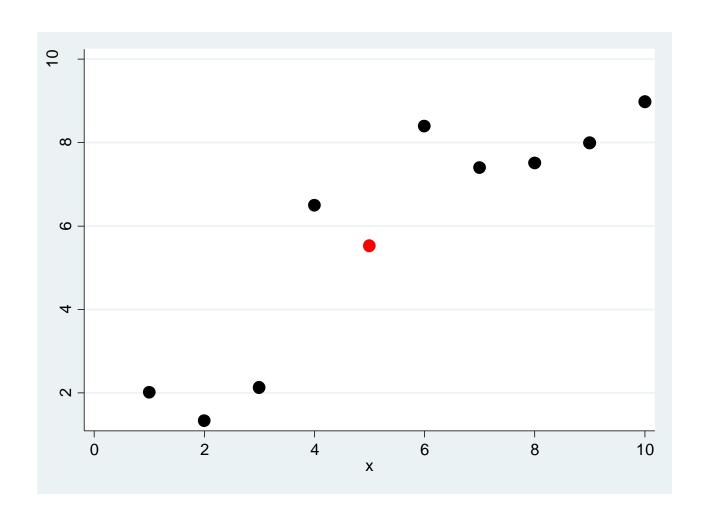

Imputation 2

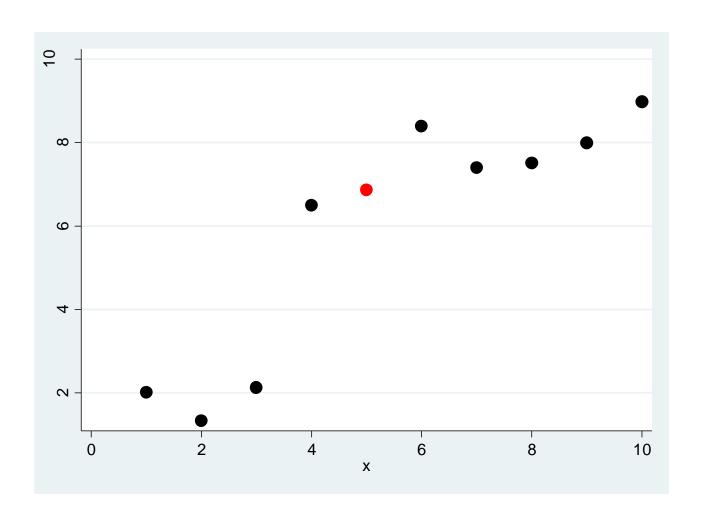

Imputation 3

Imputation 4

Imputation 5

Rubin's rules

For each dataset $i=1,\ldots,m$ we have a β_i and se_i Now want to pool these: $\beta_1 + se_1$ $\beta_2 + se_2$ $\beta + se$

Pooled β simply the average:

$$\beta = \frac{1}{m} \sum_{i=1}^{m} \beta_i$$

Pooled se slightly more complicated:

$$se(\beta) = \sqrt{\frac{1}{m} \sum_{i=1}^{m} se_i^2 + \left(1 + \frac{1}{m}\right) sd^2}$$

with sd the standard deviation of $(\beta_1, \beta_2, ..., \beta_m)$

Rubin's rules example

example

- Pooled estimated β is 5.83
- se of the pooled β is : $\sqrt{0.916^2 + (1+1/5)0.09^2} = 1.01$

What if there are several variables with missing values?

- Approach 1: Impute, assume multivariate normal distribution
 - Will also work if variables are ordinal or binary
 - For skewed distributions: first transformation

Monotone imputation method

Monotone Missing Data Patterns

Group	Y1	Y2	Υ3
1	Χ	Χ	Χ
2	Χ	Χ	
3	X		

- Impute first Y₂ with Y₁, then Y₃ with Y₂ and Y₁, etc.
- Be aware: the order of the variables matters

Chained equations (MICE)

- Fill in random values for all missing data
- Impute missing data for X₁ with X₂...X_n
- Impute missing data for X₂ with imputed X₁ and X₃...X_n etc.
- Cycling through these steps until the process is stable
- Procedure known multivariate imputation by chained equations (MICE) or fully conditional specification (FCS)
- NB: transform skewed variables first, and transform back after imputation

Y	X ₁	X ₂	X ₃
-0,3	0	0,8	-0,2
-1,9	1	-1,1	-1,4
1,8	1	0,4	0,4
1,4	1	-0,3	0,6
0,3	0	0,4	1,5
-0,1	0	0,4	0,6
-1,8	0	-0,5	0,9
-0,4	0	-0,9	0,8
0,3	1	-0,8	1,2
-0,3	1	-1,4	1

Υ	X ₁	X ₂	X ₃
-0,3		0,8	-0,2
-1,9		-1,1	-1,4
1,8	1	0,4	0,4
1,4	1	-0,3	0,6
0,3	0	0,4	1,5
-0,1	0	0,4	0,6
-1,8	0	-0,5	0,9
-0,4	0	-0,9	0,8
0,3	1		1,2
-0,3	1		1

Y	X ₁	X ₂	X ₃
-0,3	0	0,8	-0,2
-1,9	0	-1,1	-1,4
1,8	1	0,4	0,4
1,4	1	-0,3	0,6
0,3	0	0,4	1,5
-0,1	0	0,4	0,6
-1,8	0	-0,5	0,9
-0,4	0	-0,9	0,8
0,3	1	0,4	1,2
-0,3	1	0,8	1

Initialize by sampling from the observed values

Υ	X ₁	X ₂	X ₃
-0,3	0	0,8	-0,2
-1,9	0	-1,1	-1,4
1,8	1	0,4	0,4
1,4	1	-0,3	0,6
0,3	0	0,4	1,5
-0,1	0	0,4	0,6
-1,8	0	-0,5	0,9
-0,4	0	-0,9	0,8
0,3	1	0,4	1,2
-0,3	1	0,8	1

Model $X_1 \mid Y, X_2, X_3$ (e.g. a logistic regression) based only on observed X_1

Υ	X ₁	X ₂	X ₃
-0,3	1	0,8	-0,2
-1,9	0	-1,1	-1,4
1,8	1	0,4	0,4
1,4	1	-0,3	0,6
0,3	0	0,4	1,5
-0,1	0	0,4	0,6
-1,8	0	-0,5	0,9
-O,4	0	-0,9	0,8
0,3	1	0,4	1,2
-0,3	1	0,8	1

Impute! (accounting for parameter uncertainty/random variation)

Υ	X ₁	X ₂	X ₃
-0,3	1	0,8	-0,2
-1,9	0	-1,1	-1,4
1,8	1	0,4	0,4
1,4	1	-0,3	0,6
0,3	0	0,4	1,5
-0,1	0	0,4	0,6
-1,8	0	-0,5	0,9
-0,4	0	-0,9	0,8
0,3	1	0,4	1,2
-0,3	1	0,8	1

Model $X_2 \mid Y, X_1, X_3$ based using observed X_2 (e.g. a linear regression) - note that the latest imputed X_1 are used in the model

Υ	X ₁	X ₂	X ₃
-0,3	1	0,8	-0,2
-1,9	0	-1,1	-1,4
1,8	1	0,4	0,4
1,4	1	-0,3	0,6
0,3	0	0,4	1,5
-0,1	0	0,4	0,6
-1,8	0	-0,5	0,9
-O,4	0	-0,9	0,8
0,3	1	0,5	1,2
-0,3	1	0,6	1

Impute! This is now a single imputed dataset based on one iteration/cycle across the variables

General rule: enter in imputation model:

- Variables that will be used in analysis model (including the outcome !!!)
- Variables related to the missing process
- Other variables associated with the variables with missing values
- Complexity of the analysis model must also be included in the imputation (e.g. interaction terms or random effects)

Which model to use to impute?

- Continuous variables: e.g. linear regression
- Binary variables: e.g. logistic regression
- Categorical variables: e.g. multinomial logistic regression or ordinal logistic regression
- Counts: e.g. Poisson regression
- More flexible algorithms can also be used, for example mice package in R supports trees, forests, LASSO etc.

Predictive mean matching

- Alternative to imputing numeric values with a regression model: predictive mean matching (PMM)
- Uses the drawn predicted y for a missing value
- Then imputes the observed y of the person closest in prediction to the imputed value (or the mean of several persons closest by)
- Advantage: you will not obtain unrealistic values of y
- Disadvantage: variability may be underestimated
- PMM is default method to impute numeric values in the mice package in R

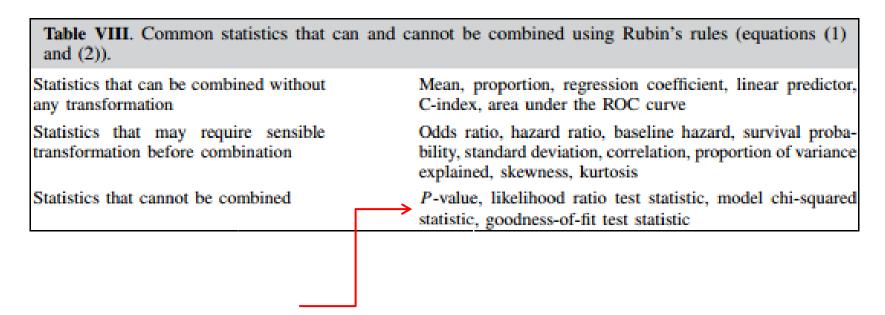

Some final tips

- Number of imputed datasets?
 - Rubin: 5
 - Use for datasets with many variables with missing values more imputation sets
 (50 or more)
 - If feasible, you may vary the number of imputations to see if this affects your results
 - Very large number helps for reproducibility but not per se for accuracy
- Imputation model should be well specified
 - Check the underlying models, are they stable?
 - Useful to first run one model for each variable separately

Some cautions

- More complicated settings:
 - survival data
 - clustered/hierarchial data
 - combining MI with bootstrapping, making predictions/validation
 - For propensity scores (Choi, Dekkers, le Cessie, 2018, Eur J Epidemiol)

Caveat: much can be pooled, but not everything

"Things that change when sample size increases"

Solution: present range over imputation runs or present results for one random set (e.g. for presenting a figure)

In summary

- First: think about the most plausible mechanism that led to the missing observations
- Second: make the DAG (explained in practical exercises)
- Choose appropriate analysis strategy (see slide 22)
- Compare observed data with imputed data: understand any differences
- Report on the assumptions made

Reading material

Reading material for exam + helpful for practical exercise:

• Lee KJ et al. The Treatment And Reporting of Missing data in Observational Studies framework. JCE 2021

Hands-on tips for performing multiple imputation:

• White IR et al. Multiple imputation using chained equations: Issues and guidance for practice. Stat Med 2011

Other sources

- A gentle introduction to imputation of missing values.
 Donders et al. JCE 2006
- Multiple imputation for missing data in epidemiological and clinical research: potential and pitfalls. Sterne et al BMJ 2009;338:b2393
- When and how should multiple imputation be used for handling missing data in randomised clinical trials – a practical guide with flowcharts. Jakobsen et al BMC Med Res Methodol. 2017.

Overview

- 1. Types of missing data (recap repeated measurements course)
- 2. Methods to deal with missing data
- 3. Multiple imputation

4. Practical exercises in R

- missing data in DAGs
- multiple imputation in R

After practical exercises: what did we learn?

- There are situations where complete case analysis yields unbiased results, even for MAR or MNAR
- Imputation will give the correct estimates (unbiased) for MAR and MCAR if the imputation model is correct
- Multiple imputation is not working well for MNAR (imputation methods to handle MNAR exist, but they require extra untestable assumptions)
- Important to think carefully about which variables to use in the imputation model, otherwise we are jumping out of the fryer pan into the fire (van de regen in de drup)
- The outcome should be added to the imputation model.
